EXPERIMENT NO: 2

APPARATUS REQUIRED: Power Supply, Digital Trainer, IC’s (7404, 7408, 7432) Connecting leads.

BRIEF THEORY: Karnaugh maps are the most extensively used tool for simplification of Boolean functions. It is mostly used for functions having up to six variables beyond which it becomes very cumbersome. In an n-variable K-map there are $2^n$ cells. Each cell corresponds to one of the combination of n variable, since there are $2^n$ combinations of n-variables. Gray code has been used for the identification of cells.

Example- $f(A, B, C, D) = A'B'C + ABC + ABC' + ABC$ (SOP)
Reduced form is $BC + AC + AB$ and POS form is $f(X, Y, Z) = Y' (X' + Y + Z') (X + Z)$

LOGIC DIAGRAM

EXPERIMENT NO: 3

Aim: Verification of State Tables of Rs, J-k, T and D Flip-Flops using NAND & NOR Gates

APPARATUS REQUIRED:  IC’ S 7400, 7402 Digital Trainer & Connecting leads.

BRIEF THEORY:

- **RS FLIP-FLOP:** There are two inputs to the flip-flop defined as R and S. When I/Ps R = 0 and S = 0 then O/P remains unchanged. When I/Ps R = 0 and S = 1 the flip-flop is switches to the stable state where O/P is 1 i.e. SET. The I/P condition is R = 1 and S = 0 the flip-flop is switched to the stable state where O/P is 0 i.e. RESET. The I/P condition is R = 1 and S = 1 the flip-flop is switched to the stable state where O/P is forbidden.

- **JK FLIP-FLOP:** For purpose of counting, the JK flip-flop is the ideal element to use. The variable J and K are called control I/Ps because they determine what the flip-flop does when a positive edge arrives. When J and K are both 0s, both AND gates are disabled and Q retains its last value.

- **D FLIP–FLOP:** This kind of flip flop prevents the value of D from reaching the Q output until clock pulses occur. When the clock is low, both AND gates are disabled D can change value without affecting the value of Q. On the other hand, when the clock is high both AND gates are enabled. In this case, Q is forced to equal the value of D. When the clock again goes low, Q retains or stores the last value of D. a D flip flop is a bistable circuit whose D input is transferred to the output after a clock pulse is received.

- **T FLIP-FLOP:** The T or "toggle" flip-flop changes its output on each clock edge, giving an output which is half the frequency of the signal to the T input. It is useful for constructing binary counters, frequency dividers, and general binary addition devices. It can be made from a J-K flip-flop by tying both of its inputs high.

EXPERIMENT NO: 4

Aim:- Implementation and Verification of Decoder/De-Multiplexer and Encoder using Logic Gates.

APPARATUS REQUIRED: IC 7447, 7-segment display, IC 74139 and connecting leads.

BRIEF THEORY:

ENCODER: An encoder is a device, circuit, transducer, software program, algorithm or person that converts information from one format or code to another, for the purposes of standardization, speed, secrecy, security, or saving space by shrinking size. An encoder has M input and N output lines. Out of M input lines only one is activated at a time and produces equivalent code on output N lines. If a device output code has fewer bits than the input code has, the device is usually called an encoder. For example Octal-to-Binary Encoder take 8 inputs and provides 3 outputs, thus doing the opposite of what the 3-to-8 decoder does. At any one time, only one input line has a value of 1. The figure below shows the truth table of an Octal-to-binary encoder.

For an 8-to-3 binary encoder with inputs I0-I7 the logic expressions of the outputs Y0-Y2 are:

\[
Y_0 = I_1 + I_3 + I_5 + I_7 \\
Y_1 = I_2 + I_3 + I_6 + I_7 \\
Y_2 = I_4 + I_5 + I_6 + I_7
\]

DECODER: A decoder is a device which does the reverse operation of an encoder, undoing the encoding so that the original information can be retrieved. The same method used to encode is usually just reversed in order to decode. It is a combinational circuit that converts binary information from n input lines to a maximum of \(2^n\) unique output lines. In digital electronics, a decoder can take the form of a multiple-input, multiple-output logic circuit that converts coded inputs into coded outputs, where the input and output codes are different. e.g. n-to-\(2^n\), binary-coded decimal decoders. Enable inputs must be on for the decoder to function, otherwise its outputs assume a single "disabled" output code word. In case of decoding all combinations of three bits eight (\(2^3=8\)) decoding gates are required. This type of decoder is called 3-8 decoder because 3 inputs and 8 outputs. For any input combination decoder outputs are 1.

DEMULTIPLEXER: Demultiplexer means generally one into many. A demultiplexer is a logic circuit with one input and many outputs. By applying control signals, we can steer the input signal to one of the output lines. The ckt. has one input signal, m control
signal and n output signals. Where $2^n = m$. It functions as an electronic switch to route an incoming data signal to one of several outputs.

Quiz Questions with answer.

Q. 1 What do you understand by decoder?
Ans. A decoder is a combinational circuit that converts binary information from n input lines to a maximum of 2n unique output lines. Most IC decoders include one or more enable inputs to control the circuit operation.

Q. 2 What is demultiplexer?
Ans. The demultiplexer is the inverse of the multiplexer, in that it takes a single data input and n address inputs. It has 2^n outputs. The address input determine which data
output is going to have the same value as the data input. The other data outputs will have the value 0.

Q. 3 What do you understand by encoder?
Ans. An encoder or multiplexer is therefore a digital IC that outputs a digital code based on which of its several digital inputs is enabled.

Q. 4 What is the main difference between decoder and demultiplexer?
Ans. In decoder we have n input lines as in demultiplexer we have n select lines.

Q. 5 Why Binary is different from Gray code?
Ans. Gray code has a unique property that any two adjacent gray codes differ by only a single bit.

Q. 6 Write down the method of Binary to Gray conversion.
Ans. Using the Ex-Or gates.

Q. 7 Convert 0101 to Decimal.
Ans. 5

Q. 8 Write the full form of ASCII Codes?

Q. 9. If a register containing 0.110011 is logically added to register containing 0.101010 what would be the result?
Ans. 111011

Q. 10. Binary code is a weighted code or not?
Ans. Yes

EXPERIMENT NO: 9

Aim:- To Design & Verify Operation of Half Adder & Full Adder.

APPARATUS REQUIRED: Power supply, IC’s, Digital Trainer, Connecting leads.

BRIEF THEORY: We are familiar with ALU, which performs all arithmetic and logic operation but ALU doesn’t perform/ process decimal no’s. They process binary no’s.

Half Adder: It is a logic circuit that adds two bits. It produces the O/P, sum & carry. The Boolean equation for sum & carry are:

\[
\text{SUM} = A + B \\
\text{CARRY} = A \cdot B
\]

Therefore, sum produces 1 when A&B are different and carry is 1 when A&B are 1. Application of Half adder is limited.

Full Adder: It is a logic circuit that can add three bits. It produces two O/P sum & carry. The Boolean Equation for sum & carry are:

\[
\text{SUM} = A + B + C \\
\text{CARRY} = A \cdot B + (A+B) \cdot C
\]

Therefore, sum produces one when I/P is containing odd no’s of one & carry is one when there are two or more one in I/P.

BRIEF THEORY:
The 74181 is a 7400 series medium-scale integration (MSI) TTL integrated circuit, containing the equivalent of 75 logic gates and most commonly packaged as a 24-pin DIP. The 4-bit wide ALU can perform all the traditional add / subtract / decrement operations with or without carry, as well as AND / NAND, OR / NOR, XOR, and shift. Many variations of these basic functions are available, for a total of 16 arithmetic and 16 logical operations on two four-bit words. Multiply and divide functions are not provided but can be performed in multiple steps using the shift and add or subtract functions. Shift is not an explicit function but can be derived from several available functions including (A+B) plus A.

AN EXAMPLE

AIM: Liquid Level Alarm

APPARATUS REQUIRED: Components as shown in the circuit diagram (such as 555 ICs, soldering iron and solder flux and PCB board).

BRIEF THEORY: Here is a simple circuit for (T1 and T2) and two timers 555 ICs (IC1 and IC2). Both IC1 and IC2 are wired in astable multivibrator mode. Timer IC1 produces low frequency, while timer IC2 produces high frequency. As a result, a beeping tone is generated when the liquid tank is full. Initially, when the tank is empty, transistor T1 does not conduct. Consequently, transistor T2 conducts and pin 4 of IC1 is low. This low voltage disables IC1 and it does not oscillate. The low output of IC1 disables IC2 and it does not oscillate. As a result, no sound is heard from the speaker. But when the tank gets filled up, transistor T1 conducts. Consequently, transistor T2 is cut off and pin 4 of IC1 becomes high. This high voltage enables IC1 and it oscillates to produce low frequencies at pin 3. This low-frequency output enables IC2 and it also oscillates to produce high frequencies. As a result, sound is produced from the speaker. Using preset VR1 you can control the volume of the sound from the speaker. The circuit can be powered from a 9V battery or from mains by using a 9V power adaptor.

CIRCUIT DIAGRAM:
PROCEDURE: Assemble the circuit on a general purpose PCB and enclose in a suitable cabinet. Install two water-level probes using metal strips such that one touches the bottom of the tank and the other touches the maximum level of the water in the tank. Interconnect the sensor and the circuit using a flexible wire.

PRECAUTIONS:

1) Make the connections according to the Circuit diagram using soldering iron
2) The connections should be tight.
3) The $V_{cc}$ and ground should be applied carefully at the specified pin only
